25. Shifting of the neutral at a vbending process of AISI 1015 steel plate

iCAST-ES 2019 Journal of Physics: Conference Series IOP Publishing doi:10.1088/1742-6596/1450/1/012126 1450 (2020) 012126

Shifting of the neutral line at a v-bending process of AISI 1015 steel plate

W Purwadi1, B Bandanadjaja1, D Idamayanti1 1 Foundry Engineering Department, Politeknik Manufaktur Bandung, Jalan Kanayakan 21, Bandung, Indonesia

Report was generated on Friday, Nov 20, 2020, 10:34 AM

E-mail: wiwik@polman-bandung.ac.id

Abstract. During <u>a forming</u> process of steel plate <u>microstructural</u> changes <u>occurs</u> in the material. The <u>outside</u> part of the material experiences tension while compression stress takes place in the inner side. Constant uniaxial load, speed and temperature were applied on the V bending of 4 mm thick low carbon steel plate. <u>Microstructural observation and hardness test were carried</u> <u>out on the cross-section</u> area of the plate to assess the changes within the material. It is revealed that an offset of the imaginary neutral line to the inner side has occurred. The elongation of stretched material on the outer side, which is associated with microstructural changes of grain shape, orientation and hardness value does not exceed the proportional plastic area.

Introduction

Deformation in the bending process

V bending is one of the most common forming technologies that is applicable in sheet metal forming. In V bending processes the sheet material was cut in angles of 0°, 45° and ²²90° throughout the rolling direction. and ²³the obtained spring-back and -go amounts were examined ²⁴after the bending process [1]. The effect of material thickness on bending processes was reported ²⁵in previous studies [2].

Stress state

The influence of plate thickness has been observed. Stress state determination numerical analysis during the bending process was applied by using.

228

SimufactForming v10 program package [3]. It was found that there is no significant difference in values of stress for different sheet thicknesses. Figure 1 shows the stress state of plate for various thickness.

Grain deformation

Microstructural characterization and deformation of X10CrAlSi24 Sheet Material by applying V- Bending process has been carried out [4]. It was observed that at 4 mm thick steel plate the increased bending angle had remarkable effect o, the grain orientation and crack that might be occured. The grain orientation is mostly tangential to the center of the bending radii.

Grain size, orientation and ⁴⁴/₁₅ influence to the mechanical properties The hardness is mainly governed by the average grain size and is independent of the grain shape or the grain aspect ratio. The ductility (in terms of the reduction in area) is influenced by the grain aspect ratio. ⁴⁷ In contrast, the ultimate tensile strength is independent of the grain aspect ratio but shows an explicit dependency on the specimen orientation [5]. The change in grain size accompanies a plastic deformation determines the change ⁴⁸/₁₅ strength ⁴⁹/₀ f a polycrystalline material as ⁵⁰/₅₀ by decreasing the grain diameter. Hardness itself is defined ⁵²/₅₄ sthe ability of a material to resist against ⁵³/₅₇ the penetration of other harder ⁵⁴/₅₀ by the material.⁵⁸

When a quasi-static deformation occur, the mechanical properties are controlled ⁶⁰ by processing parameters (strain, strain rate, deformation temperature and ⁶¹ cooling rate). The level of grain size modification does not cause any significant deviations in material behavior comparing to coarsegrained ⁶² microstructures [6].

Design of experiment

Material

For the purposes of 64 his study low 65 carbon steel plates 64 AISI 1015 with the size of 200mm length, 20 mm width and 67 mm thick were used. Table 1 describes the chemical composition of the material.

Table 1. Elemental composition of sample.

Initial microstructure and normalizing condition ^{70,71} The initial material has inhomogenous grain shape, grain orientation and grain size, which might cause any distortion. Normalizing is carried out on the material to homogenize the microstructure and eliminating stresses caused by the previous rolling process. ⁷³ The material is heated up to 900°C and followed by air cooling.

Speed and temperature of bending

231

Since ⁷⁴Cracks can evenly be distributed all over the surface of plates and are oriented in the rolling direction and in ⁷⁵most cases cracks ⁷⁶ are fully ⁷⁷filled with an iron oxide [7]. Steel plate has therefore to be grinded to produce a smooth

surface and minimize the occurance of crack ⁸³ initiating notch. Bending is carried out ⁸⁴ on samples with V bending tools to form 90⁸⁵ plate. The bending process is done ⁸⁶ constant ⁸⁷ speed of ⁸⁸ 120 mm.s-1 and ambient ⁸⁹ temperature of 23°C.

Measuring the strain

Prior to ⁹⁰ the bending process ⁹¹ samples are marked at 4 positions as described in the figure ⁹³ 2. The distance b is equal to one eighth of the inner circumference, which corresponds to 45° of bending. Two lines are marked within b in a similar distance, ⁹⁵ so that three bands are obtained. ⁹⁶ The elongation after completion of the bending is determined ⁹⁷ calculating the difference between the final distance ⁹⁸ of strips and the initial distance. ⁹⁹ The elongation value is then compared and analysed ¹⁰⁰ with the tensile diagram of the material.

Figure 2. Marking line of samples.

Measuring the hardness

Hardness test is carried out at several position along the marking lines I to IV Microvickers hardness testing as per ASTM E-384 is considered the suitable method for analysing the mechanical properties of material. Small load of the test enables the measurement of two indentation at a closer distance. For materials in which plastic deformation is predominant, the influence of the load on the measured value of micro-hardness is statistically significant. The relationship between applied load and microhardness manifests reverse Indentation Size Effect (ISE) for all annealing temperatures [8]. Along with the observation of microstructure and elongation value, hardness value indicates a change of material properties due to the bending process. Figure 3. Area of observation.

Microstructural observation

Microstructural test consists of testing of grain shapes, grain orientation and grain dimension. Grain shape is determined by the shape factor resulting from the ratio of two perpendicular diagonal. Grain orientation described the angle between the longer diagonal of grain and the center line ¹¹⁴ ¹¹⁵. A study on the microstructure evolution of mechanically formed samples under varying load conditions has been reported [9]. It concluded that the grain sizes of the deformed mild steel plate showed elongated grains and ¹¹⁷ it was directly proportional to the applied loads. ¹¹⁸ Finally, the study showed that the grain size elongation and hardness obtained in the deformed samples were linearly dependent on the applied loads. Metallographic examinations are therefore carried out on the pre-determined spots along the lines as described in Figure 3. For this <u>purpose</u> an optical microscope is used on the already prepared samples.

Results and discussion The examination is described in average value for each of the test result.

Strain at the inner side and outer side at various position

Table 2 shows the deformation of the samples which ¹²³ indicated by the elongation at inner side and outer side of the bending radii. ¹²⁵ The inner side in ¹²⁶ general does not experience significant elongation, whereas the outer side is elongated up ¹³⁰ 15.9%. The maximum elongation remains nevertheless in the area of proportional plastic deformation.

Table 2. Elongation at the bending radii. outer side 7.80 8.80 12.82 band II inner side 7.80 7.82 0.26 outer side 7.80 8.94 14.62 band III inner side 7.80 7.80 0.00 outer side 7.80 9.04

initial (mm) final (mm) elongation % band I inner side 7.80 7.82 0.26

Hardness vickers¹³² Hardness value of the material at the bending side is described in the Table 3 Compared to the middle part of the cross-section area, the inner side and the outer side of the bending radii show higher value respectively. The Increasing hardness shows that the material has undergone a plastic deformation by using a non linier regression formula, the lowest hardness was calculated. It indicates the lowest internal¹⁴⁴

stress ¹⁴⁵ in the material which ¹⁴⁶ can furthermore <u>be considered</u> ¹⁴⁷ as the neutral area. A neutral line was <u>then then</u> achieved by connecting each point of the lowest state of internal stress.

3.2 mm from the inner side, measured on the cross section area. ¹⁵⁴ ¹⁵⁴ outer side of the bending radii, measured on the surface of sample.

Microstructural observation

Figure 4 shows the micrograph of the sample at various positions. During the bending process¹⁵⁹ he outer side of the sample was stretched and experienced ¹⁶³ ¹⁶⁴ therefore tension stress, which is indicated with the elongated grain (flattening of the grain). ¹⁶⁶ ¹⁶⁷ ⁴⁶, 4f and ¹⁶⁸ describe the microstructure of the outer side. The grain directions in this side are mostly perpendicular to the centreline. This tensile stress stress after dies displacement is consistent with the previous work by Min Zhang [12], which prooved that the metal farther away from the neutral axis was stressed beyond the yield strength, and plastically or permanently deformed. The micrographs reveal also the differences in grain roughness in the middle and sides of the sample. Microstructure in the middle ¹⁷⁵ part of the sample is almost the same as the initial condition prior to the deformation. The grain at the inner side is slightly smaller than the initial condition. The microstructure was composed of ferrite grains and pearlite can be shown in Figure 4.

Figure 4. Micrograph of material.

Discussion

As shown in the Figure 5 the center line of bending (Line IV) exhibit the highest increase of hardness. ¹⁸⁷Higher deformation on this site is considerably the cause of the microstructural change and its mechanical properties. It complies also ¹⁸⁹ with the flattened grain of microstructure and its orientation. At the inner side compressive load occures on the material, which produces furthermore slightly smaller grain. ¹⁹²The grain orientation is herewith nearly parallel to the centerline of the bending radius.

The result complied with the previous study [10], which declared that mechanical properties of metal strongly depend on the microstructure. The influence becomes more significant with decreasing thickness. The stress at the inner side results in the increase ¹⁹⁵ of ^{196,197} of hardness. The lowest hardness value

for each area has been determined and located mostly close to the centerline of sample. Lower hardness value can be considered as lower state of internal stress in the material, which complies in this case with the initial condition of ^{204,205} sample and can therefore be determined as the neutral area. However the lowest hardness area shifts slightly to the inner side of bending radii [11].

Figure 5. Hardness value in average.

Conclusions

The bending process results in plastic deformation due to tension stress on the outside and compression stress on the inside. Grain size, orientation and shape change related to the degree of deformation. Microstructure and properties of the material at crosssection area varies related to the distance to the inner side. The most deformed part (outer side) as indicated by the elongation value shows finer, flattened grain and high hardness value. The neutral line which imaginary connects areas of lowest energy in the cross section area shifts slightly to the center of the bending radius.
